SHEP-11-17

Trimaximal neutrino mixing from vacuum alignment in A_4 and S_4 models

Stephen F. King* and Christoph Luhn†

School of Physics and Astronomy, University of Southampton, Southampton, SO17 1BJ, United Kingdom

Abstract

Recent T2K results indicate a sizeable reactor angle θ_{13} which would rule out *exact* tri-bimaximal lepton mixing. We study the vacuum alignment of the Altarelli-Feruglio A_4 family symmetry model including additional flavons in the $\mathbf{1}'$ and $\mathbf{1}''$ representations and show that it leads to trimaximal mixing in which the second column of the lepton mixing matrix consists of the column vector $(1,1,1)^T/\sqrt{3}$, with a potentially large reactor angle. In order to limit the reactor angle and control the higher order corrections, we propose a renormalisable S_4 model in which the $\mathbf{1}'$ and $\mathbf{1}''$ flavons of A_4 are unified into a doublet of S_4 which is spontaneously broken to A_4 by a flavon which enters the neutrino sector at higher order. We study the vacuum alignment in the S_4 model and show that it predicts *accurate* trimaximal mixing with *approximate* tri-bimaximal mixing, leading to a new mixing sum rule testable in future neutrino experiments. Both A_4 and S_4 models preserve form dominance and hence predict zero leptogenesis, up to renormalisation group corrections.

1 Introduction

Recently T2K have published evidence for a large non-zero reactor angle [1] which, when combined with data from MINOS and other experiments in a global fit yields [2],

$$\theta_{13} = 8^\circ \pm 1.5^\circ, \tag{1.1}$$

where the errors indicate the one σ range, although the statistical significance of a non-zero reactor angle is about 3σ.

If confirmed this would rule out the hypothesis of exact tri-bimaximal (TB) mixing [3]. However other schemes such as trimaximal (TM) mixing remain viable [4–8]:

$$U_{\rm TM} \;=\; P' \begin{pmatrix} \frac{2}{\sqrt{6}}\cos\vartheta & \frac{1}{\sqrt{3}} & \frac{2}{\sqrt{6}}\sin\vartheta\, e^{i\rho} \\ -\frac{1}{\sqrt{6}}\cos\vartheta - \frac{1}{\sqrt{2}}\sin\vartheta\, e^{-i\rho} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}}\cos\vartheta - \frac{1}{\sqrt{6}}\sin\vartheta\, e^{i\rho} \\ -\frac{1}{\sqrt{6}}\cos\vartheta + \frac{1}{\sqrt{2}}\sin\vartheta\, e^{-i\rho} & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}}\cos\vartheta - \frac{1}{\sqrt{6}}\sin\vartheta\, e^{i\rho} \end{pmatrix} P \;, \tag{1.2}$$

where $\frac{2}{\sqrt{6}}\sin\vartheta = \sin\theta_{13}$, P' is a diagonal phase matrix required to put $U_{\rm TM}$ into the PDG convention [9], and $P = {\rm diag}(1, e^{i\frac{\alpha_2}{2}}, e^{i\frac{\alpha_3}{2}})$ contains the usual Majorana phases. In particular TM mixing approximately preserves the successful TB mixing for the solar mixing angle $\theta_{12} \approx 35^\circ$ as the correction due to a non-zero but relatively small reactor angle is of second order. Although TM mixing reduces to TB mixing in the limit that $\vartheta \to 0$, it is worth emphasising that in general TM mixing involves a reactor angle θ_{13} which could in principle be large or even maximal (e.g. 45°). The observed smallness of the reactor angle θ_{13} compared to the atmospheric angle $\theta_{23} \approx 45^\circ$ and the solar angle $\theta_{12} \approx 34^\circ$ [2] is therefore not explained by the TM hypothesis alone. Clearly the relative smallness of the reactor angle can only be explained with additional model dependent input. We shall show that, although an A_4 family symmetry can provide an explanation of trimaximal mixing, the observed smallness of the reactor angle as compared to the atmospheric and solar angles may be naturally explained by an S_4 family symmetry.

In the original A_4 models of TB mixing Higgs fields [10] or flavons [11,12] transforming under A_4 as **3** and **1** but not $\mathbf{1}'$ or $\mathbf{1}''$ were used to break the family symmetry and to lead to TB mixing. However there is no good reason not to include flavons transforming as $\mathbf{1}'$ or $\mathbf{1}''$ and once included they will lead to deviations from TB mixing [13,14] in particular it has been noted that they lead to TM mixing [15]. However, as remarked above, TM mixing by itself does not account for the smallness of the reactor angle, and in particular the model in [15] does not provide any explanation for this. Another aspect is that higher order operators in A_4 models lead to deviations from TB mixing in a rather uncontrolled way [12], and in such models any simple TM structure may be washed out unless the theory is promoted to a renormalisable one in which the higher order operators are under control. For example, this was done for two A_4 models of TB mixing in [16], and one may follow an analogous strategy including also $\mathbf{1}'$ or $\mathbf{1}''$ flavons.

In this paper we make a first study of the vacuum alignment of an A_4 family symmetry model of leptons with additional flavons in the $\mathbf{1}'$ and/or $\mathbf{1}''$ representations and show that it leads to *accurate* trimaximal mixing at leading order (LO). In order to constrain the reactor angle and control the higher order corrections, we then propose a renormalisable

S_4 model of leptons in which the $\mathbf{1}'$ and $\mathbf{1}''$ flavons of A_4 are unified into a doublet of S_4 which is spontaneously broken to A_4 by a flavon which enters the neutrino sector at higher order. We study the vacuum alignment of the S_4 model and show that it predicts *accurate* trimaximal mixing with *approximate* tri-bimaximal mixing, leading to a new mixing sum rule testable in future neutrino experiments. We also remark that both A_4 and S_4 models preserve form dominance [17] and hence predict zero leptogenesis [18], up to renormalisation group corrections.

The layout of the rest of the paper is as follows. In Section 2 we first revisit the Altarelli-Feruglio A_4 model [12] with regard to the possibility of generating deviations from TB mixing which respect TM mixing. As the obvious ideas do not yield TM mixing, we then consider the model augmented by extra flavons in the $\mathbf{1}'$ and/or $\mathbf{1}''$ representation. We study the vacuum alignment and show that this model leads to TM mixing, with an unconstrained reactor angle. In Section 3 we propose a renormalisable S_4 model of leptons and study its vacuum alignment leading to *accurate* trimaximal mixing with *approximate* tri-bimaximal mixing. In Section 4 we give an analytic discussion of the perturbative deviations to TB mixing arising from any TM model with a physical reactor angle leading to a new mixing sum rule testable in future neutrino experiments. Section 5 concludes the paper. Appendix A contains Clebsch-Gordon coefficients for S_4 and A_4, and Appendix B describes a perturbative diagonalisation of the right-handed neutrino mass matrix.

2 A_4 models of trimaximal mixing

2.1 The Altarelli-Feruglio A_4 model of tri-bimaximal mixing

The original and well studied Altarelli-Feruglio (AF) model of lepton masses and mixings [12] is formulated as an effective theory, defined purely by the particle content and the symmetries. There exist two versions, one with right-handed neutrinos and one without. For definiteness we will only consider the former which makes use of the elegant seesaw mechanism to obtain effective light neutrino masses around the eV scale. The particle content and the symmetries of the AF model we consider is presented in Table 1, including the ξ flavon, but excluding the ξ' and ξ'' flavons which we shall consider later. In addition the vacuum alignment in the AF model requires a further auxiliary flavon singlet $\tilde{\xi}$ which does not acquire a VEV and is not shown in the table. Particles with a $U(1)_R$ charge of 2 are called driving fields. Setting their F-terms to zero leads to the F-term conditions which control the alignment of the flavon fields.

The relevant effective superpotential terms of the Yukawa sector of the AF model are

$$W_{A_4}^{\rm eff} \;\sim\; LH_u N^c + (\varphi_S + \xi) N^c N^c + \frac{1}{M} H_d \Big[(L\varphi_T)_1 \, e^c + (L\varphi_T)_{1'} \, \mu^c + (L\varphi_T)_{1''} \, \tau^c \Big] \; . \quad (2.1)$$

Here $(\cdots)_r$ denotes the contraction of the A_4 indices to the representation $\mathbf{r}$. When the three flavon fields $\varphi_S, \xi, \varphi_T$ acquire their VEVs [12],

$$\langle \varphi_S \rangle = v_S \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \; , \qquad \langle \xi \rangle = u \; , \qquad \langle \varphi_T \rangle = v_T \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \; , \quad (2.2)$$

at some high scale, the flavour structure of the Yukawa couplings is generated which, after electroweak symmetry breaking, gives rise to a trivial Dirac neutrino mass matrix m_D, a TB heavy right-handed neutrino mass matrix M_R as well as a diagonal charged lepton mass matrix m_ℓ. Applying the seesaw formula yields a TB light neutrino mass matrix which is diagonalised by $U_{\rm TB} = U_{\rm TM}(\vartheta = 0)$. With the charged leptons being already diagonal, the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) mixing matrix becomes $U_{\rm PMNS} = U_{\rm TB}$. The reason why the AF A_4 model preserves TB mixing is that the flavon φ_S preserves the S generator of A_4 and the absence of ξ' and ξ'' flavons leads to an accidental U symmetry, where S, U symmetry in the neutrino sector and T symmetry in the charged lepton sector implies TB mixing (see e.g. [19]).

This result is correct at LO. It is argued in [12] that higher order operators which are allowed by the imposed symmetries should be considered as well, both in $W_{A_4}^{\rm eff}$ as well as in the superpotential that generates the flavon alignments in Eq. (2.2). In general such additional terms would lead to deviations from TB mixing which are important in the light of the latest experimental hints for a non-zero reactor angle [1, 2]. In order to account for a (relatively) large value of θ_{13} the higher order corrections need to be large enough which can be arranged by assuming different suppression scales for different non-renormalisable operators. This assumption, however, raises the question about the origin of the suppression scales.

In this context, it was pointed out recently that particular ultraviolet (UV) completions of flavour models do not necessarily give rise to all effectively allowed terms in the superpotential [16]. In fact, it was found that the minimal UV completion of the AF model does not generate any deviations from TB mixing. The simplest way to obtain the desired deviations is to add new messengers to the minimal model such that certain higher order Yukawa operators are switched on. In the neutrino sector, the effective non-trivial operators allowed by the symmetries read[1]

$$\frac{1}{M}\Big[(N^cN^c)_{1'}(\varphi_S\varphi_T)_{1''}+(N^cN^c)_{1''}(\varphi_S\varphi_T)_{1'}+(N^cN^c)_3(\varphi_S\varphi_T)_{3_{s,a}}+(N^cN^c)_3(\xi\varphi_T)_3\Big], \quad (2.3)$$

all of which break TB neutrino mixing. Inspection of the flavour structure of these terms shows that only the first two terms lead to mass matrices that have an eigenvector $\frac{1}{\sqrt{3}}(1,1,1)^T$, thus retaining TM neutrino mixing. However, requiring the messengers that

[1]Note that the third term, corresponding to two independent contractions, was not listed in Eq. (32) of [12] despite giving non-trivial contributions to the mass matrix, i.e. contributions that differ from the tri-bimaximal structure.

mediate these effective operators to be matter-like, i.e. they should have a $U(1)_R$ charge of 1, we find that we will always get a contribution from the third term of Eq. (2.3) as well. Therefore, without introducing new flavon fields, we cannot find a simple UV completion of the AF model where the neutrino mixing features a trimaximal pattern while breaking the tri-bimaximal one.

2.2 Trimaximal mixing from A_4 with extra ξ' and ξ'' flavons

The discussion in the previous subsection leads us to consider the case where extra flavons ξ' in the $\mathbf{1}'$ representation and ξ'' in the $\mathbf{1}''$ representations of A_4 are added to the model as already shown in Table 1. This has previously been suggested (without the see-saw mechanism) in [15] where the phenomenological consequences of the LO terms were studied numerically. However the flavon alignment was not derived in [15] but simply postulated. Remarkably, although the difference between the ξ' and ξ'' flavon VEVs breaks the accidental U symmetry and thereby violates TB mixing, the presence of these flavons respects the S symmetry and leads to TM mixing.

In this subsection we consider the effect on the neutrino mass matrices of adding flavons ξ' in the $\mathbf{1}'$ representation and/or ξ'' in the $\mathbf{1}''$ representations. In the subsequent subsection we consider the vacuum alignment problem including these flavons. Assuming the flavon alignments in Eq. (2.2), it is straightforward to find the structure of the charged lepton and the light neutrino mass matrices. As the charged lepton Yukawa couplings are non-renormalisable, a particular set of messengers is necessary to generate the required couplings. Following [16], one can show that a minimal messenger completion does not generate any off-diagonal entries in m_ℓ. Therefore, the leptonic mixing matrix $U_{\rm PMNS}$ is solely determined by the neutrino sector. Given the symmetries of Table 1, the corresponding renormalisable neutrino part of the superpotential is extended to,

$$W^{\nu}_{A_4} \;=\; yLH_uN^c + (y_1\varphi_S + y_2\xi + y'_3\xi' + y''_3\xi'')N^cN^c \;. \tag{2.4}$$

Inserting the flavon vacuum alignments in Eq. (2.2), and assuming both ξ' and ξ'' as well as SM Higgs VEVs, we obtain the Dirac neutrino mass matrix m_D as well as the right-handed neutrino mass matrix M_R,

$$m_D \;=\; \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} y\, v_u \;, \tag{2.5}$$

$$M_R \;=\; \left[\alpha \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix} + \beta \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} + \gamma' \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} + \gamma'' \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \right] \;, \tag{2.6}$$

where $\alpha = y_1 v_S$, $\beta = y_2\langle\xi\rangle$, $\gamma' = y'_3\langle\xi'\rangle$, $\gamma'' = y''_3\langle\xi''\rangle$.

The complex symmetric matrix M_R is diagonalised by a unitary transformation U_R,

$$U_R^T M_R U_R \;=\; M_R^{\rm diag} \;. \tag{2.7}$$

One can easily verify that $\frac{1}{\sqrt{3}}(1,1,1)^T$ is an eigenvector of $M_R^\dagger M_R$, the eigenvalue being $|(\beta+\gamma'+\gamma'')|^2$. Therefore the matrix U_R will have a trimaximally mixed column which, for phenomenological reasons, will be identified as the second column. The other two columns are more difficult to determine and we will discuss the analytic approximate calculation in Section 4. However, they can be parameterised as a linear combination of the first and third columns of the TB mixing matrix $U_{\rm TB}$. Thus U_R is of the form given in Eq. (1.2), with the parameters ϑ and ρ being functions of the Yukawa couplings and VEVs. Note that a Majorana phase matrix would still have to be multiplied on the right in order to render the right-handed neutrino masses real. Disregarding this and other issues about phase conventions, we can now rewrite the effective light neutrino mass matrix,

$$m_\nu^{\rm eff} = -m_D M_R^{-1} m_D^T = -m_D U_R (M_R^{\rm diag})^{-1} U_R^T m_D^T = -U_\nu \, \frac{(y\, v_u)^2}{M_R^{\rm diag}} \, U_\nu^T \ , \qquad (2.8)$$

where the matrix U_ν is defined as

$$U_\nu \ = \ \frac{m_D}{y v_u} \, U_R \ . \qquad (2.9)$$

Due to the trivial structure of m_D, see Eq. (2.5), it is unitary and again of trimaximal form. In fact, U_ν differs from U_R only in the interchange of the second and the third row. Assuming diagonal charged leptons, the matrix U_ν is just the lepton mixing matrix $U_\nu = U_{\rm PMNS}$. From Eq. (2.8) it is then apparent that the Dirac neutrino mass matrix in the basis of diagonal right-handed neutrinos and charged leptons, is given by $m_D' = y v_u U_{\rm PMNS}$. In this basis, the columns of m_D' are proportional to the columns of $U_{\rm PMNS}$, and thus we see that the A_4 model with additional ξ' and ξ'' flavons satisfies form dominance [17] and hence leptogenesis vanishes [18].[2] However, form dominance does not imply that the effective light neutrino mass matrix is form diagonalisable, and indeed this is not the case since the mixing matrix U_ν depends on the Yukawa couplings and VEVs (which in turn determine the neutrino masses). Only in the limit where $\gamma' = \gamma''$ do we recover a form diagonalisable mass matrix corresponding to the TB case.

The size of the deviations from TB mixing are controlled by the parameters y_3' and y_3'' as well as the VEVs $\langle\xi'\rangle$ and $\langle\xi''\rangle$. From the vacuum alignment discussion in the next subsections, however, there is no reason to believe that these VEVs should be small, i.e. one would expect a large reactor angle as well as large deviations from maximal atmospheric mixing. In order to meet the experimental bounds, one would therefore have to assume the input parameters of the flavon and Yukawa superpotential to conspire so as to yield only small deviations from the TB mixing pattern. Eventually this will motivate us to go beyond A_4 to S_4 where the two extra flavons ξ' and ξ'' are unified into a doublet representation.

[2] This conclusion can be avoided by taking into account renormalisation group corrections which effect the entries of the Dirac neutrino Yukawa matrix differently so that the orthogonality of the columns is broken [20].

2.3 Vacuum alignment in A_4 with extra ξ' and ξ'' flavons

In this subsection we scrutinise the modifications to the alignment mechanism of Altarelli and Feruglio due to the addition of flavons ξ' in the $\mathbf{1}'$ and/or ξ'' in the $\mathbf{1}''$ representation of A_4. Our main result is that contrary to [12] one need not introduce the auxiliary flavon singlet $\tilde{\xi}$ which does not acquire a VEV and so plays no direct role in the flavour structure of the neutrinos. In that sense the introduction of a ξ' and/or ξ'' flavon does not only serve the purpose of breaking the TB structure to a TM one, but also does not complicate the model at all.

The renormalisable terms of the driving superpotential, replacing the $\tilde{\xi}$ flavon of the AF model by the ξ' and ξ'' flavons, are,

$$\begin{aligned} W_{A_4}^{\text{flavon}} &= \varphi_T^0 \left(M\varphi_T + g\varphi_T\varphi_T\right) + \varphi_S^0 \left(g_1\varphi_S\varphi_S + g_2\varphi_S\xi + g_3'\varphi_S\xi' + g_3''\varphi_S\xi''\right) \\ &\quad + \xi^0 \left(g_4\varphi_S\varphi_S + g_5\xi\xi + g_6\xi'\xi''\right) . \end{aligned} \tag{2.10}$$

As the F-term equations of φ_T^0 remain unchanged from the AF model, we obtain - up to some A_4 transformed solutions - the well known alignment

$$\langle\varphi_T\rangle = v_T \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} , \qquad v_T = -\frac{M}{2g} . \tag{2.11}$$

On the other hand, the F-term conditions of φ_S^0 and ξ^0 are slightly modified in this new setup. Writing $\langle\varphi_{Si}\rangle = s_i$ and $\langle\xi\rangle = u$, $\langle\xi'\rangle = u'$ and $\langle\xi''\rangle = u''$,we get

$$2g_1 \begin{pmatrix} s_1^2 - s_2 s_3 \\ s_3^2 - s_1 s_2 \\ s_2^2 - s_3 s_1 \end{pmatrix} + g_2 u \begin{pmatrix} s_1 \\ s_2 \\ s_3 \end{pmatrix} + g_3' u' \begin{pmatrix} s_3 \\ s_1 \\ s_2 \end{pmatrix} + g_3'' u'' \begin{pmatrix} s_2 \\ s_3 \\ s_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} , \tag{2.12}$$

$$g_4(s_1^2 + 2s_2 s_3) + g_5 u^2 + g_6 u' u'' \;=\; 0 \; . \tag{2.13}$$

For simplicity, let us first consider the case where only one of the two non-trivial one-dimensional flavons is present. For definiteness we assume this to be the ξ'. It is then straightforward to work out the most general solutions to Eqs. (2.12,2.13). Again, disregarding the ambiguity caused by A_4 symmetry transformations we find two possible non-trivial solutions,

$$\langle\varphi_S\rangle = v_S \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} , \qquad v_S^2 = -\frac{g_5}{3g_4} u^2 , \qquad u' = -\frac{g_2}{g_3'} u , \tag{2.14}$$

as well as

$$\langle\varphi_S\rangle = v_S \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} , \qquad v_S = -\frac{g_3'}{2g_1} u' , \qquad u = 0 . \tag{2.15}$$

Choosing the soft mass parameter $m_\xi^2 < 0$, the second solution is eliminated and the VEV u slides to a large scale [12]. In this way we are able to get the original alignment of φ_S and non-vanishing VEVs for ξ and ξ', see Eq. (2.14).

We now consider the effect of having both flavons ξ' and ξ'' in the $\mathbf{1}'$ and $\mathbf{1}''$ representations of A_4. Then the terms proportional to g_3'' and g_6 would be switched on in the flavon superpotential of Eq. (2.10) The corresponding extra terms in the F-term conditions of Eqs. (2.12,2.13) would thus modify the physical solution of Eq. (2.14) to

$$\langle \varphi_S \rangle = v_S \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, \qquad v_S^2 = -\frac{g_5 u^2 + g_6 u' u''}{3 g_4}, \qquad u = -\frac{g_3' u' + g_3'' u''}{g_2}. \tag{2.16}$$

This solution has the unpleasant feature of leading to arbitrary physics. For instance, if $y_3' u' = y_3'' u''$, where y_3'' denotes the Yukawa coupling of ξ'' to $N^c N^c$, see Eq. (2.4), then this implies that the mass matrix M_R in Eq. (2.6) has a tri-bimaximal structure, since $\gamma' = \gamma''$, and thus the reactor angle vanishes identically. It is for this reason that models with *either* ξ' *or* ξ'' essentially yield the same physics. However, adding both types of flavons in A_4 generates a bothersome ambiguity in physical predictions. In the next section the above ambiguity is removed by unifying the flavons ξ' and ξ'' into an S_4 doublet η_ν, whose VEV components are aligned along a U preserving direction, thereby restoring TB mixing, at least approximately.

3 S_4 model of trimaximal mixing

3.1 The effective S_4 model of leptons

As pointed out in the previous section, the A_4 model with ξ' and/or ξ'' flavons cannot explain the smallness of the deviations from TB mixing. Furthermore, adding both non-trivial one-dimensional flavons leads to an ambiguity in physical predictions. In order to cure these shortcomings we consider an S_4 model in which the $\mathbf{1}'$ and $\mathbf{1}''$ representations of A_4 are unified into the η_ν doublet of S_4 while the triplet representations remain. The complete list of lepton, Higgs and flavon fields is given in Table 2.[3] Similar to the A_4 model we have a $U(1)_R$ symmetry as well as a Z_3 symmetry which separates the neutrino and the charged lepton sector.

In the neutrino sector of the S_4 model there are three flavon fields: φ_ν and ξ_ν (analogous to φ_S and ξ of the AF model) and η_ν (which unifies the two A_4 flavon fields ξ' and ξ''). The neutrino part of the effective superpotential is then,

$$W_{S_4}^{\nu,\text{eff}} \;\sim\; L H_u N^c + (\varphi_\nu + \xi_\nu + \eta_\nu) N^c N^c + \frac{\zeta_\nu}{M_\chi}\, \eta_\nu N^c N^c, \tag{3.1}$$

analogous to Eq. (2.4), where, as in the A_4 model, the Dirac neutrino mass matrix takes the trivial form m_D of Eq. (2.5). However an additional flavon ζ_ν in the $\mathbf{1}'$ representation

[3] In principle the triplet fields can either be identified with the $\mathbf{3}$ or the $\mathbf{3}'$ of S_4. They differ from each other only in the sign of the U generator (see Appendix A) such that all representation matrices of the $\mathbf{3}$ have determinant $+1$, while this is not the case for the $\mathbf{3}'$. In the case of the right-handed neutrinos N^c and the lepton doublet L, we are free to choose the type of S_4 triplet as long as it is the same for both fields, and we choose the $\mathbf{3}$. Note that the triplet flavon φ_ν must furnish a $\mathbf{3}'$ of S_4 because it is coupled to the *symmetric* product $N^c N^c$.

	N^c	L	e^c	μ^c	τ^c	H_u	H_d	φ_ℓ	η_μ	η_e	φ_ν	η_ν	ξ_ν	ζ_ν
S_4	$\mathbf{3}$	$\mathbf{3}$	$\mathbf{1}$	$\mathbf{1}$	$\mathbf{1'}$	$\mathbf{1}$	$\mathbf{1}$	$\mathbf{3'}$	$\mathbf{2}$	$\mathbf{2}$	$\mathbf{3'}$	$\mathbf{2}$	$\mathbf{1}$	$\mathbf{1'}$
Z_3	ω^2	ω	ω^2	ω^2	ω^2	1	1	1	1	1	ω^2	ω^2	ω^2	1
Z_3'	1	1	1	ω	ω^2	1	1	ω	ω	ω^2	1	1	1	1
$U(1)_R$	1	1	1	1	1	0	0	0	0	0	0	0	0	0

Table 2: Lepton, Higgs and flavon fields of the S_4 model.

of S_4 serves the purpose of breaking S_4 to A_4. The U violating flavon ζ_ν is forbidden by S_4 to couple to N^cN^c at renormalisable level but appears at higher order, thereby breaking the TB structure by a small amount, leading to a non-zero but suppressed reactor angle, while preserving the TM structure due to the unbroken S symmetry. Inserting the flavon VEVs, whose alignment is discussed later,

$$\langle\varphi_\nu\rangle = v_\nu \begin{pmatrix}1\\1\\1\end{pmatrix}, \qquad \langle\eta_\nu\rangle = w_\nu \begin{pmatrix}1\\1\end{pmatrix}, \qquad \langle\xi_\nu\rangle = u_\nu\ , \qquad \langle\zeta_\nu\rangle = z_\nu\ , \tag{3.2}$$

$W_{S_4}^{\nu,\text{eff}}$ leads to TB neutrino mixing at LO, broken to TM mixing by the non-vanishing VEV for the ζ_ν flavon at next-to-leading order (NLO). Note that the neutrino sector above may readily be incorporated without change into an $SU(5)$ GUT as was done for A_4 and S_4 models of TB mixing along the lines of [21–24].

In order to account for the charged lepton mass hierarchy we identify the right-handed charged leptons with one-dimensional representations of S_4, and distinguish them by an extra Z_3' family symmetry, broken by a triplet flavon φ_ℓ as well as the doublet flavons η_μ, η_e, resulting in the effective charged lepton superpotential,

$$W_{S_4}^{\ell,\text{eff}} \ \sim\ \frac{\varphi_\ell}{M_{\Omega_1}} H_d \left[L\tau^c + \frac{\eta_\mu}{M_{\Omega_2}} L\mu^c + \frac{\eta_e}{M_{\Omega_3}} Le^c \right]\ , \tag{3.3}$$

where M_{Ω_i} are *a priori* independent mass scales, although two of the mass scales will turn out to be equal, $M_{\Omega_2} = M_{\Omega_3}$. Inserting the flavon VEVs,

$$\langle\varphi_\ell\rangle = v_\ell \begin{pmatrix}0\\1\\0\end{pmatrix}\ , \qquad \langle\eta_\mu\rangle = w_\mu \begin{pmatrix}0\\1\end{pmatrix}\ , \qquad \langle\eta_e\rangle = w_e \begin{pmatrix}1\\0\end{pmatrix}\ , \tag{3.4}$$

whose alignment is discussed later, and using the Clebsch-Gordan coefficients listed in Appendix A, leads to

$$W_{S_4}^{\ell,\text{eff}} \ \sim\ \frac{v_\ell H_d}{M_{\Omega_1}} \left[L_3\tau^c + \frac{w_\mu}{M_{\Omega_2}} L_2\mu^c + \frac{w_e}{M_{\Omega_3}} L_1 e^c \right]\ , \tag{3.5}$$

resulting in a diagonal charged lepton mass matrix m_ℓ. The larger τ lepton mass is explained by the fact that the e and μ masses are only provided at higher order by two

	φ_ℓ^0	η_ℓ^0	ξ_ℓ^0	φ_ν^0	$\tilde{\varphi}_\nu^0$	ξ_ν^0	D^0	χ	χ^c	Ω_1	Ω_1^c	Ω_2	Ω_2^c

Table 3: Driving fields and messengers of the S_4 model.

additional doublet flavons η_μ, η_e. The electron to muon mass hierarchy is accounted for by a hierarchy of flavon VEVs $w_e \ll w_\mu$, which can be obtained consistently assuming certain hierarchies in the mass parameters of the flavon superpotential. Such large hierarchies of VEVs are of course stable in SUSY models, and are already familiar due to the hierarchy between the weak scale and the flavour or GUT scales. Finally note that the charged lepton sector above will eventually require modification as was done for A_4 and S_4 models of TB mixing in order to be incorporated into an $SU(5)$ GUT since quark mixing requires some small off-diagonal mixing also in the charged lepton sector [21–24].

3.2 The renormalisable S_4 model of leptons

As emphasised earlier, any non-renormalisable term of an effective superpotential should be understood in terms of a more fundamental underlying renormalisable theory. Without such a UV completion of a model, higher order terms which are allowed by the symmetries may or may not be present. Thus a purely effective formulation would leave room for different physical predictions. In order to remove any such ambiguity within our S_4 model we have constructed a fully renormalisable theory of the lepton sector. The required messengers are listed in Table 3, together with the driving fields which control the alignment of the flavons.

With the particle content and the symmetries specified in Tables 2 and 3, we can replace the effective neutrino superpotential in Eq. (3.1) by the sum of two renormalisable pieces, a LO piece and a messenger piece,

$$W_{S_4}^{\nu} = W_{S_4}^{\nu,\mathrm{LO}} + W_{S_4}^{\nu,\mathrm{mess}} \,, \tag{3.6}$$

where,

$$W_{S_4}^{\nu,\mathrm{LO}} = y L H_u N^c + (y_1 \varphi_\nu + y_2 \xi_\nu + y_3 \eta_\nu) N^c N^c \,, \tag{3.7}$$

$$W_{S_4}^{\nu,\mathrm{mess}} = x_1 N^c \zeta_\nu \chi + \chi^c (x_2 \eta_\nu + x_3 \varphi_\nu) N^c + M_\chi \chi \chi^c \,. \tag{3.8}$$

The leading order contribution to the right-handed neutrino mass matrix M_R is given by $W_{S_4}^{\nu,\mathrm{LO}}$ and leads to a TB structure. Given a non-vanishing VEV for the ζ_ν flavon, $W_{S_4}^{\nu,\mathrm{mess}}$ is responsible for breaking the TB structure to a TM one at higher order. The corresponding LO and NLO diagrams are depicted in Figure 1.[4] Integrating out the

[4]We remark that we have suppressed the additional messenger terms $(\varphi_\nu + \eta_\nu + \xi_\nu)\chi^c\chi^c$ which are

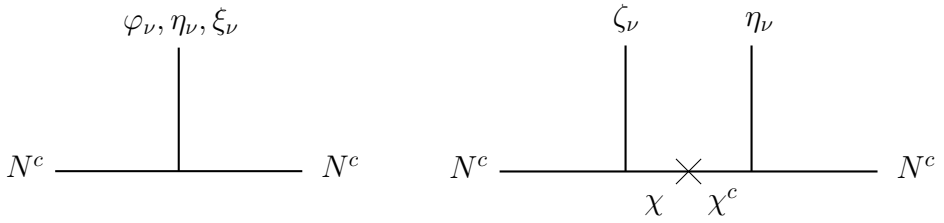

Figure 1: Leading and next-to-leading order right-handed neutrino mass contributions.

messenger pair χ, χ^c, the NLO diagram reproduces uniquely the effective operator in Eq. (3.1), $\frac{\zeta_\nu}{M_\chi}\,\eta_\nu N^c N^c$. Note that a similar term with η_ν replaced by φ_ν is forbidden by S_4 as the symmetric product $N^c N^c$ does not include the triplet **3**. Plugging in the flavon VEVs and using the S_4 Clebsch-Gordan coefficients of Appendix A we obtain a contribution to M_R of the form

$$\Delta M_R \;=\; x_1 x_2\,\frac{w_\nu z_\nu}{M_\chi}\left[-\begin{pmatrix}0&0&1\\0&1&0\\1&0&0\end{pmatrix}+\begin{pmatrix}0&1&0\\1&0&0\\0&0&1\end{pmatrix}\right]. \tag{3.9}$$

The relative minus sign arises as the ζ_ν VEV breaks the U symmetry of S_4. Its presence leads to a deviation from the TB structure which would exist if the two matrices were added instead.

The S_4 model thus gives rise to TB neutrino mixing at LO which is broken to a TM mixing pattern by NLO corrections induced by the VEV of the S_4 breaking flavon field ζ_ν. This naturally explains why the reactor angle as well as the deviations from maximal atmospheric mixing are relatively small. Provided the charged leptons are diagonal, the lepton mixing matrix is purely determined by the structure of the right-handed neutrino mass matrix M_R, given in Eq. (2.6), with

$$\alpha = y_1 v_\nu\ , \qquad \beta = y_2 u_\nu\ , \qquad \gamma' = \gamma - \Delta\ , \qquad \gamma'' = \gamma + \Delta\ , \tag{3.10}$$

where we have defined

$$\gamma = y_3 w_\nu\ , \qquad \Delta = x_1 x_2 \frac{w_\nu z_\nu}{M_\chi}\ . \tag{3.11}$$

Notice that γ' and γ'' are equal at LO. The deviations from a TB mass matrix arise only at NLO which is parameterised by $\frac{\Delta}{\gamma} \sim \frac{z_\nu}{M_\chi}$.

The charged lepton sector is formulated at the renormalisable level, using two new pairs of messengers, Ω_i and Ω_i^c $(i = 1, 2)$. With the particles and symmetries listed in

allowed in $W_{S_4}^{\nu,\mathrm{mess}}$ since they become relevant only at next-to-next-to-leading order with the ζ_ν flavon entering quadratically; as the Klein symmetry $Z_S \times Z_U$ of the neutrino sector [19] is restored in this diagram by the quadratic appearance of ζ_ν, such a higher order term yields a TB contribution to M_R. Therefore, the only significant term contributing to the breaking of TB to TM is the one shown in Figure 1.

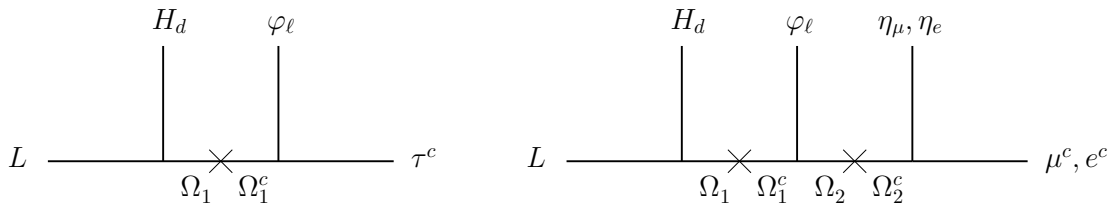

Figure 2: S_4 diagrams that lead to a diagonal charged lepton sector.

Tables 2 and 3, we get the renormalisable superpotential for the charged leptons,

$$\begin{aligned} W_{S_4}^{\ell} &\sim LH_d\Omega_1 + \Omega_1^c\varphi_\ell\tau^c + \Omega_1^c\varphi_\ell\Omega_2 + \Omega_2^c\eta_\mu\mu^c + \Omega_2^c\eta_e e^c \\ &\quad + M_{\Omega_1}\Omega_1\Omega_1^c + (M_{\Omega_2} + \zeta_\nu)\Omega_2\Omega_2^c \,, \end{aligned} \tag{3.12}$$

where we have suppressed all order one coupling constants. The appearance of ζ_ν in the second line leads to an irrelevant correction of the Ω_2 messenger mass which we ignore in the following. Integrating out the messengers, we obtain the diagrams of Figure 2 leading uniquely to $W_{S_4}^{\ell,\text{eff}}$ in Eq. (3.3), with $M_{\Omega_2} = M_{\Omega_3}$.

3.3 Vacuum alignment in the S_4 model

So far we have only postulated the particular alignments of the neutrino-type flavons, given in Eq. (3.2), and the flavons of the charged lepton sector, Eq. (3.4). In this subsection we first explore the driving potential relevant for the neutrino sector and prove that the assumed alignment can in fact be obtained in an elegant way which is similar to the A_4 case. Then we perform a similar study of the flavon alignments for the charged leptons.

The renormalisable superpotential involving the driving fields necessary for aligning the neutrino-type flavons is given as

$$\begin{aligned} W_{S_4}^{\text{flavon},\nu} &= \varphi_\nu^0(g_1\varphi_\nu\varphi_\nu + g_2\varphi_\nu\xi_\nu + g_3\varphi_\nu\eta_\nu) + \xi^0(g_4\varphi_\nu\varphi_\nu + g_5\xi_\nu\xi_\nu + \frac{g_6}{2}\eta_\nu\eta_\nu) \\ &\quad + g_7\tilde{\varphi}_\nu^0\varphi_\nu\eta_\nu + D^0(f_1\zeta_\nu\zeta_\nu + f_2\eta_\mu\eta_e + f_3 H_u H_d + f_4 M_0^2) \,. \end{aligned} \tag{3.13}$$

Identifying the two components of the doublet flavon η_ν with ξ'' and ξ', the first line of Eq. (3.13) is identical to the corresponding terms in the A_4 driving superpotential of Eq. (2.10). Due to the S_4 structure, we additionally get $g_3' = g_3'' = g_3$. All other common coupling constants g_i $(i = 1, ..., 6)$ appear in exactly the same way once the S_4 and A_4 indices are expanded out. As identical equations yield identical results, the first line of Eq. (2.10) gives rise to an alignment which suffers from the same ambiguity as the alignment of Eq. (2.16): the ratio of the VEVs of the two doublet flavon components, i.e. $\frac{\langle\eta_{\nu,1}\rangle}{\langle\eta_{\nu,2}\rangle}$, remains a free parameter. This ambiguity can be removed by introducing the driving field $\tilde{\varphi}_\nu^0$ in the **3** representation of S_4. As φ_ν furnishes a $\mathbf{3'}$ representation, we only get one coupling, proportional to g_7, at the renormalisable level. With φ_ν already being aligned in the $(1,1,1)^T$ direction, the resulting F-term condition enforces equal VEVs for

$\eta_{\nu,1}$ and $\eta_{\nu,2}$. In this minimal and elegant way we have obtained the structure of the S_4 alignments given in Eq. (3.2), with

$$v_\nu^2 = -\frac{1}{3g_4}\left[g_5 + g_6\left(\frac{g_2}{2g_3}\right)^2\right]u_\nu^2 \ , \qquad w_\nu = -\frac{g_2}{2g_3}u_\nu \ . \tag{3.14}$$

As in the AF model, the VEV u_ν is driven to a non-zero value due to $m_{\xi_\nu}^2 < 0$.

The remaining terms of the flavon superpotential of Eq. (3.13) are responsible for driving the VEV of the ζ_ν flavon in the $\mathbf{1'}$ representation of S_4. As the driving field D^0 is completely neutral under the imposed discrete symmetries, compare Table 3, we additionally encounter Higgs fields as well as flavons of the charged lepton sector. The former do not play any role in aligning the flavons as the S_4 breaking is typically assumed to occur around the GUT scale. Therefore we can safely set $f_3 = 0$. This leaves us with an F-term condition that intertwines the ζ_ν flavon with the flavons η_μ and η_e of the charged lepton sector. A simple way to disentangle the flavons of the two sectors was put forward in [24]. The idea is to introduce a second driving field with identical quantum numbers as D^0. Then one obtains two F-term conditions which are identical in their structure but involve independent coupling constants, f_i for one driving field and f_i' for the other. As both conditions must be satisfied, one can linearly combine the equations and thus find a unique solution for the VEV of the ζ_ν flavon,

$$z_\nu^2 = -\frac{f_4 f_2' - f_2 f_4'}{f_1 f_2' - f_2 f_1'}M_0^2 \ . \tag{3.15}$$

Turning to the flavon alignment of the charged lepton sector, the renormalisable driving superpotential takes the form

$$\begin{aligned} W_{S_4}^{\text{flavon},\ell} &= \varphi_\ell^0(h_1\varphi_\ell\varphi_\ell + h_2\varphi_\ell\eta_\mu) + \xi_\ell^0(h_3\varphi_\ell\varphi_\ell + h_4\eta_\mu\eta_\mu) \\ &\quad + \eta_\ell^0(M_2\eta_e + h_5\zeta_\nu\eta_e + h_6\eta_\mu\eta_\mu + h_7\varphi_\ell\varphi_\ell) \ . \end{aligned} \tag{3.16}$$

The alignments of the flavon fields φ_ℓ and η_μ are constrained by the first line of Eq. (3.16). Writing $\langle\varphi_{\ell i}\rangle = t_i$ and $\langle\eta_{\mu_i}\rangle = r_i$, the F-term conditions read

$$2h_1\begin{pmatrix} t_1^2 - t_2t_3 \\ t_3^2 - t_1t_2 \\ t_2^2 - t_3t_1 \end{pmatrix} + h_2r_1\begin{pmatrix} t_2 \\ t_3 \\ t_1 \end{pmatrix} + h_2r_2\begin{pmatrix} t_3 \\ t_1 \\ t_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} , \tag{3.17}$$

$$h_3(t_1^2 + 2t_2t_3) + 2h_4r_1r_2 \ = \ 0 \ . \tag{3.18}$$

The most general solution to these equations can be obtained by a straightforward calculation. As a result one finds two solutions,

$$\langle\varphi_\ell\rangle = v_\ell\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \ , \qquad \langle\eta_\mu\rangle = w_\mu\begin{pmatrix} 0 \\ 1 \end{pmatrix} \ , \qquad v_\ell = -\frac{h_2}{2h_1}\,w_\mu \ , \tag{3.19}$$

as well as

$$\langle\varphi_\ell\rangle = v_\ell \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \ , \qquad \langle\eta_\mu\rangle = w_\mu \begin{pmatrix} 1 \\ -1 \end{pmatrix} \ , \qquad v_\ell^2 = \frac{2h_4}{3h_3}\, w_\mu^2 \ . \tag{3.20}$$

Clearly, alignments which are derived from these by application of an arbitrary S_4 transformation also satisfy the F-term conditions of Eqs. (3.17,3.18).[5] In order to get rid of the second solution we can use the idea of adding a second ξ_ℓ^0 driving field [24], thus effectively splitting the F-term condition of Eq. (3.18) into two equations,

$$(t_1^2 + 2t_2 t_3) = 0 \ , \qquad r_1 r_2 = 0 \ . \tag{3.21}$$

Then the remaining solution, i.e. Eq. (3.19), is just what we have used in the discussion of the charged lepton flavour structure, see Eq. (3.4).

Having fixed the alignment of φ_ℓ and η_μ we can now proceed with the alignment of the flavon doublet η_e. This is determined from the F-term condition of the driving field η_ℓ^0 in Eq. (3.16). Inserting the VEVs of φ_ℓ, η_μ and ζ_ν, and writing $\langle\eta_{e,i}\rangle = q_i$ we obtain

$$M_2 \begin{pmatrix} q_1 \\ q_2 \end{pmatrix} + h_5 z_\nu \begin{pmatrix} q_1 \\ -q_2 \end{pmatrix} + h_6 w_\mu^2 \begin{pmatrix} 1 \\ 0 \end{pmatrix} + h_7 v_\ell^2 \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} . \tag{3.22}$$

As z_ν is already fixed, $q_2 = 0$ and we find the η_e alignment of Eq. (3.4) with

$$w_e = -\frac{h_6 w_\mu^2 + h_7 v_\ell^2}{M_2 + h_5 z_\nu} \ . \tag{3.23}$$

Finally, we have to consider the terms of $W_{S_4}^{\mathrm{flavon},\nu}$ proportional to the driving field D^0, see Eq. (3.13). Repeating the discussion above Eq. (3.15), the η_μ and η_e VEVs are simultaneously driven to non-vanishing values with

$$w_\mu w_e = -\frac{f_4 f_1' - f_1 f_4'}{f_2 f_1' - f_1 f_2'} M_0^2 \ . \tag{3.24}$$

We conclude this section by sketching how the hierarchy of charged lepton masses might be obtained in our setup. We will adopt a very rough approximation, dropping all order one coefficients and keeping only orders of magnitude. Everything must be explained in terms of the input mass parameters M_0 and M_2 of Eqs. (3.13,3.16) as well as the involved messenger masses. Assuming

$$M_2 \ \sim \ 1000\, M_0 \ , \tag{3.25}$$

we get

$$v_\ell \sim w_\mu \sim 10\, M_0 \ , \qquad w_e \sim \frac{1}{10}\, M_0 \ . \tag{3.26}$$

This yields a hierarchy of about 100 between the muon and the electron mass. Setting the messenger masses M_{Ω_i} at a scale of around $100 M_0$ fixes the ratio between the tau and the muon mass at a value of order 10. The tau mass itself is then set to be approximately $\frac{v_d}{10}$.

[5] For a discussion of why such S_4 symmetry transformed solutions lead to the same physics see [23].

4 Trimaximal mixing in terms of perturbative deviations to tri-bimaximal mixing

In this section we make a perturbative and analytic study of the deviations to TB mixing which are predicted by the A_4 and S_4 models of TM mixing, subject to the phenomenological constraint that the reactor angle is perturbatively small, which enables TM mixing to be viewed as a perturbative expansion around the TB limit. This is natural from the point of view of S_4 models where TB mixing arises at LO, broken by higher order corrections which preserve TM mixing. It also enables alternative phenomenological proposals to be viewed and compared on the same footing.

Our starting point is the right-handed neutrino mass matrix of the A_4 model in Eq. (2.6). It can be written as the sum of a matrix that preserves TB mixing and a matrix that violates it,

$$M_R = M_R^{\rm TB} + \Delta M_R \ , \tag{4.1}$$

where

$$M_R^{\rm TB} \ = \ \alpha \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix} + \beta \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} + \gamma \begin{pmatrix} 0 & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix} \ , \tag{4.2}$$

and

$$\Delta M_R = \Delta \begin{pmatrix} 0 & 1 & -1 \\ 1 & -1 & 0 \\ -1 & 0 & 1 \end{pmatrix} \ , \tag{4.3}$$

with

$$\Delta = \tfrac{1}{2}(\gamma'' - \gamma') \ , \qquad \gamma = \tfrac{1}{2}(\gamma' + \gamma'') \ . \tag{4.4}$$

In the S_4 model the explicit form of ΔM_R is given in Eq. (3.9). In both the A_4 and S_4 models the TB violating matrix is required to be small,

$$|\Delta| \ll |\alpha|, |\beta| \ . \tag{4.5}$$

This assumption is necessary in order to meet the experimental constraints that any deviations from TB mixing should be small. The parameter γ on the other hand need not be small as it does not break the TB pattern.

Since $M_R^{\rm TB}$ is diagonalised by the TB mixing matrix $U_{\rm TB}$, this enables M_R to be diagonalised perturbatively by expanding about the TB mixing case. Writing the matrix U_R which diagonalises the right-handed neutrino mass matrix in terms of its column vectors Φ_i,

$$U_R \ = \ (\Phi_1, \Phi_2, \Phi_3) \ , \tag{4.6}$$

we can expand U_R, for small deviations from TB mixing, in linear approximation around its TB form using

$$\Phi_i \ = \ \Phi_i^{\rm TB} + \Delta\Phi_i \ , \qquad \Delta\Phi_i \ = \ \sum_j \alpha_{ij} \Phi_j^{\rm TB} \ , \tag{4.7}$$

where $\Phi_i^{\rm TB}$ are just the columns of the TB mixing matrix. As shown in Appendix B, due to the unitarity of U_R and the special form of the mass matrix M_R in Eq. (4.1), the only non-zero parameter is $\alpha_{13} = -\alpha_{31}^*$ whose dependence on the input parameters $\alpha, \beta, \gamma, \Delta$ is given in Eqs. (B.15,B.16). The fact that only $\alpha_{13} = -\alpha_{31}^*$ is non-zero implies that U_R is of TM form as expected. Furthermore, since,

$$U_R^T M_R U_R \;=\; M_R^{\rm diag} \;, \tag{4.8}$$

it is then straightforward to derive the lepton mixing matrix $U_{\rm PMNS}$, as in Eq. (2.9),

$$U_{\rm PMNS} \;=\; \frac{m_D}{y v_u}\, U_R \;. \tag{4.9}$$

Due to the trivial structure of m_D as well as a diagonal charged lepton sector, the PMNS mixing matrix can thus be directly obtained from U_R by permuting the second and the third row as well as multiplying the Majorana phase matrix P on the right and another phase matrix P' on the left, leading to $U_{\rm PMNS} = U_{\rm TM}$ where,

$$U_{\rm TM} \;\approx\; P' \begin{pmatrix} \frac{2}{\sqrt{6}} & \frac{1}{\sqrt{3}} & -\frac{2}{\sqrt{6}}\alpha_{13}^* \\ -\frac{1}{\sqrt{6}} + \frac{1}{\sqrt{2}}\alpha_{13} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{6}}\alpha_{13}^* \\ -\frac{1}{\sqrt{6}} - \frac{1}{\sqrt{2}}\alpha_{13} & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{6}}\alpha_{13}^* \end{pmatrix} P \;. \tag{4.10}$$

The matrix P' has to be chosen such that the PMNS matrix without Majorana phases is brought to the standard PDG form where the 2-3 and 3-3 elements are real and the mixing angles are all between 0° and 90°. In linear approximation, the required form of P' becomes

$$P' \;\approx\; {\rm diag}(1, a_+, -a_-) \;, \qquad a_\pm \;=\; 1 \pm i \cdot \frac{{\rm Im}(\alpha_{13})}{\sqrt{3}} \;. \tag{4.11}$$

Multiplying this explicit form of the phase matrix P' we obtain a mixing matrix that is consistent with the standard PDG phase conventions.

It is useful to compare the TM mixing matrix in Eq. (4.10) to a general parametrisation of the PMNS mixing matrix in terms of deviations from TB mixing [25],

$$U_{\rm PMNS} \approx \begin{pmatrix} \frac{2}{\sqrt{6}}(1 - \frac{1}{2}s) & \frac{1}{\sqrt{3}}(1+s) & \frac{1}{\sqrt{2}} r e^{-i\delta} \\ -\frac{1}{\sqrt{6}}(1 + s - a + r e^{i\delta}) & \frac{1}{\sqrt{3}}(1 - \frac{1}{2}s - a - \frac{1}{2} r e^{i\delta}) & \frac{1}{\sqrt{2}}(1+a) \\ \frac{1}{\sqrt{6}}(1 + s + a - r e^{i\delta}) & -\frac{1}{\sqrt{3}}(1 - \frac{1}{2}s + a + \frac{1}{2} r e^{i\delta}) & \frac{1}{\sqrt{2}}(1-a) \end{pmatrix} P \;, \tag{4.12}$$

where the deviation parameters s, a, r are defined as [25],

$$\sin\theta_{12} = \frac{1}{\sqrt{3}}(1+s) \;, \qquad \sin\theta_{23} = \frac{1}{\sqrt{2}}(1+a) \;, \qquad \sin\theta_{13} = \frac{r}{\sqrt{2}} \;. \tag{4.13}$$

This comparison yields

$$s \;\approx\; 0 \;, \quad a \;\approx\; \frac{{\rm Re}\,(\alpha_{13})}{\sqrt{3}} \;, \quad r\cos\delta \;\approx\; -\frac{2}{\sqrt{3}}\,{\rm Re}\,(\alpha_{13}) \;, \quad \delta \;\approx\; \arg\,(\alpha_{13}) + \pi \;, \tag{4.14}$$

where δ is the CP violating oscillation phase of the lepton sector, and α_{13} is proportional to Δ as shown in Eqs. (B.15,B.16). Independently of the value of α_{13} we confirm the TM sum rules given in [26],

$$s \approx 0 \ , \qquad a \approx -\frac{1}{2} r \cos\delta \ . \tag{4.15}$$

We emphasise that the sum rules in Eq. (4.15) hold for any model of trimaximal mixing, since it is always the case that phenomenology requires that it has approximate tri-bimaximal form. The above perturbative form of TM mixing in terms of TB deviation parameters is useful when comparing TM mixing to other proposed forms of the mixing matrix. For example, if the reactor angle is measured to be sizeable, but the solar and atmospheric angles remain close to their tri-bimaximal values, i.e. the deviation parameters in Eq. (4.13) take the form $s \approx a \approx 0$ but $r \neq 0$, then the mixing matrix takes the "tri-bimaximal-reactor" (TBR) form [26]. Such a mixing has recently been obtained in an S_4 setup [27]. Alternative proposals [28–40] that have been put forward to accommodate the T2K result could similarly be compared using the deviation parameters s, a, r. With future neutrino oscillation experiments being able to not only accurately measure the reactor angle, parametrised here as r, but also the atmospheric and solar deviation parameters a, s and eventually the CP violating oscillation phase δ, it is clear that relating these deviation parameters via sum rules comprise the next step in discriminating different models of lepton masses and mixings.

5 Conclusions

In the well known direct models of tri-bimaximal (TB) mixing, based on A_4 and S_4, the TB mixing is enforced by a Klein symmetry $Z_2^S \times Z_2^U$ in the neutrino sector, together with a Z_3^T symmetry in the charged lepton sector, where a common basis corresponds to a diagonal charged lepton mass matrix. It is also well known that TB mixing can emerge from either S_4, which contains the generators S, T, U, or A_4, which contains S, T. In the case of A_4 the U symmetry emerges accidentally as a result of the absence of flavons in the $\mathbf{1}'$ or $\mathbf{1}''$ representations of A_4. Such models are called "direct models" since (some of) the group generators remain unbroken in different sectors of the low energy effective theory. Although this simple and appealing picture is apparently shattered by the T2K results, which indicate a sizeable reactor angle θ_{13}, simple alternative possibilities such as trimaximal (TM) mixing remain.

We have argued that, in the framework of direct A_4 models, the T2K results motivate adding the "missing" flavons $\mathbf{1}'$ or $\mathbf{1}''$, whose VEVs break the accidental U symmetry but preserve the S symmetry in the neutrino sector corresponding to a Z_2^S subgroup of A_4, leading to a TM pattern of mixing as in Eq. (1.2). We have studied the vacuum alignment of such an extended Altarelli-Feruglio A_4 family symmetry model including additional flavons in the $\mathbf{1}'$ and $\mathbf{1}''$ representations and show that it leads to TM mixing in which the second column of the lepton mixing matrix consists of the column vector $(1,1,1)^T/\sqrt{3}$. However there are drawbacks to this approach. To begin with, the higher order corrections need to be kept under control otherwise they can wash out the desirable

TM structure, however this can in principle be done by formulating the theory at the renormalisable level. Furthermore, this approach within A_4 provides no explanation for why the reactor angle should be smaller than the atmospheric and solar angles.

In order to overcome these drawbacks, we have proposed a renormalisable S_4 model of leptons in which the $\mathbf{1}'$ and $\mathbf{1}''$ flavons of A_4 are unified into a doublet of S_4 which is spontaneously broken to A_4 by a $\mathbf{1}'$ flavon of S_4. We have studied the vacuum alignment in the S_4 model and shown that it predicts *accurate* TM neutrino mixing due to a preserved Z_2^S symmetry in the neutrino sector, where $Z_2^S \subset Z_2^S \times Z_2^U \subset S_4$. In the S_4 model, the U generator corresponding to Z_2^U is broken by the $\mathbf{1}'$ flavon of S_4, which however only enters the neutrino sector at higher order, resulting in *approximate* TB mixing.

Although the A_4 and S_4 models of leptons presented here involve diagonal charged lepton mass matrices, when the models are extended to include quarks, for example in the framework of $SU(5)$ unification, we would expect the charged lepton sectors (but not the neutrino sectors) of these models to be modified. This could introduce additional contributions to lepton mixing from the charged lepton sector. Interestingly both the A_4 and S_4 models here preserve form dominance and hence predict zero leptogenesis, independently of charged lepton mixing, up to renormalisation group corrections.

It should be clear that a sizeable reactor angle as indicated by T2K does not rule out the family symmetry approach, on the contrary it provides additional input which helps to refine the symmetry approach. In particular we have explored an S_4 model in which the leading order Klein symmetry $Z_2^S \times Z_2^U$ associated with TB mixing is broken at higher order down to a Z_2^S subgroup capable of enforcing a simple TM mixing pattern. We emphasise that the smoking gun signature of TM mixing is accurate trimaximal solar mixing $s \approx 0$, together with the sum rule $2a + r\cos\delta \approx 0$, which can be tested in forthcoming high precision neutrino oscillation experiments.

A S_4 and A_4 Clebsch-Gordan coefficients

Finite groups can be defined in terms of their generating elements which satisfy certain product rules, the so called presentation. Starting from these rules it is possible to work out the matrix representations of these elements up to an ambiguity related to the choice of basis. In the literature there exist different 'standard' choices which all have advantages but also disadvantages. As the Clebsch-Gordan coefficients depend on the chosen basis, it is necessary to carefully define the basis in which a model is constructed.

S_4	A_4	S	T	U
$\mathbf{1},\mathbf{1}'$	$\mathbf{1}$	1	1	± 1
$\mathbf{2}$	$\begin{pmatrix}\mathbf{1}''\\ \mathbf{1}'\end{pmatrix}$	$\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}$	$\begin{pmatrix}\omega & 0\\ 0 & \omega^2\end{pmatrix}$	$\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$
$\mathbf{3},\mathbf{3}'$	$\mathbf{3}$	$\frac{1}{3}\begin{pmatrix}-1 & 2 & 2\\ 2 & -1 & 2\\ 2 & 2 & -1\end{pmatrix}$	$\begin{pmatrix}1 & 0 & 0\\ 0 & \omega^2 & 0\\ 0 & 0 & \omega\end{pmatrix}$	$\mp\begin{pmatrix}1 & 0 & 0\\ 0 & 0 & 1\\ 0 & 1 & 0\end{pmatrix}$

Table 4: The generators S,T,U of S_4 and S,T of A_4 as used in this article.

The generators and Clebsch-Gordan coefficients of $S_4 = \Delta(24)$ and $A_4 = \Delta(12)$ in a basis where the triplets are explicitly real were derived in a general way in [41, 42]. As was argued in [12], there exists a more suitable triplet basis for A_4 models in which the order-three generator T is brought to a diagonal and complex form. By now this choice has become the standard or physical basis for direct models [19]. The corresponding basis in the case of S_4 can be found for instance in [43]. As A_4 is a subgroup of S_4 it is natural to express this relation also in terms of the generators where the elements S,T,U generate S_4, while A_4 is obtained by simply dropping the U generator [44].

Table 4 lists the generators of S_4 and A_4 in the physical basis. The primed representations of S_4 differ only in the sign of the U generator. Dropping the U generator we obtain A_4. It is clear from the table that the doublet of S_4 becomes a reducible representation under A_4, denoted by $\mathbf{1}''$ and $\mathbf{1}'$.

The S_4 product rules in the chosen basis are listed below, where we use the number of primes within the expression

$$\boldsymbol{\alpha}^{(\prime)} \otimes \boldsymbol{\beta}^{(\prime)} \;\to\; \boldsymbol{\gamma}^{(\prime)} \;, \tag{A.1}$$

to classify the results. We denote this number by n, e.g. in $\mathbf{3}\otimes\mathbf{3}'\to\mathbf{3}'$ we get $n=2$.

$$\mathbf{1}^{(\prime)}\otimes\mathbf{1}^{(\prime)} \;\to\; \mathbf{1}^{(\prime)} \quad \left\{ \begin{array}{ll} n=\text{even} & \begin{array}{l}\mathbf{1}\otimes\mathbf{1}\;\to\;\mathbf{1}\\ \mathbf{1}'\otimes\mathbf{1}'\;\to\;\mathbf{1}\\ \mathbf{1}\otimes\mathbf{1}'\;\to\;\mathbf{1}'\end{array} \end{array} \right\} \quad \alpha\beta \;,$$

$$\mathbf{1}^{(\prime)}\otimes\mathbf{2} \;\to\; \mathbf{2} \quad \left\{ \begin{array}{ll} n=\text{even} & \mathbf{1}\otimes\mathbf{2}\;\to\;\mathbf{2}\\ n=\text{odd} & \mathbf{1}'\otimes\mathbf{2}\;\to\;\mathbf{2}\end{array} \right\} \quad \alpha\begin{pmatrix}\beta_1\\ (-1)^n\beta_2\end{pmatrix},$$

$$\mathbf{1}^{(\prime)}\otimes\mathbf{3}^{(\prime)} \;\to\; \mathbf{3}^{(\prime)} \quad \left\{ \begin{array}{ll} n=\text{even} & \begin{array}{l}\mathbf{1}\otimes\mathbf{3}\;\to\;\mathbf{3}\\ \mathbf{1}'\otimes\mathbf{3}'\;\to\;\mathbf{3}\\ \mathbf{1}\otimes\mathbf{3}'\;\to\;\mathbf{3}'\\ \mathbf{1}'\otimes\mathbf{3}\;\to\;\mathbf{3}'\end{array} \end{array} \right\} \quad \alpha\begin{pmatrix}\beta_1\\ \beta_2\\ \beta_3\end{pmatrix},$$

$$\mathbf{2}\otimes\mathbf{2} \;\to\; \mathbf{1}^{(\prime)} \quad \left\{ \begin{array}{ll} n=\text{even} & \mathbf{2}\otimes\mathbf{2}\;\to\;\mathbf{1}\\ n=\text{odd} & \mathbf{2}\otimes\mathbf{2}\;\to\;\mathbf{1}'\end{array} \right\} \quad \alpha_1\beta_2+(-1)^n\alpha_2\beta_1 \;,$$

$$\mathbf{2} \otimes \mathbf{2} \to \mathbf{2} \quad \left\{ n = \text{even} \quad \mathbf{2} \otimes \mathbf{2} \to \mathbf{2} \right\} \quad \begin{pmatrix} \alpha_2\beta_2 \\ \alpha_1\beta_1 \end{pmatrix},$$

$$\mathbf{2} \otimes \mathbf{3}^{(\prime)} \to \mathbf{3}^{(\prime)} \quad \left\{ \begin{array}{ll} n = \text{even} & \mathbf{2} \otimes \mathbf{3} \to \mathbf{3} \\ & \mathbf{2} \otimes \mathbf{3}' \to \mathbf{3}' \\ n = \text{odd} & \mathbf{2} \otimes \mathbf{3} \to \mathbf{3}' \\ & \mathbf{2} \otimes \mathbf{3}' \to \mathbf{3} \end{array} \right\} \quad \alpha_1 \begin{pmatrix} \beta_2 \\ \beta_3 \\ \beta_1 \end{pmatrix} + (-1)^n \alpha_2 \begin{pmatrix} \beta_3 \\ \beta_1 \\ \beta_2 \end{pmatrix},$$

$$\mathbf{3}^{(\prime)} \otimes \mathbf{3}^{(\prime)} \to \mathbf{1}^{(\prime)} \quad \left\{ \begin{array}{ll} n = \text{even} & \mathbf{3} \otimes \mathbf{3} \to \mathbf{1} \\ & \mathbf{3}' \otimes \mathbf{3}' \to \mathbf{1} \\ & \mathbf{3} \otimes \mathbf{3}' \to \mathbf{1}' \end{array} \right\} \quad \alpha_1\beta_1 + \alpha_2\beta_3 + \alpha_3\beta_2 \,,$$

$$\mathbf{3}^{(\prime)} \otimes \mathbf{3}^{(\prime)} \to \mathbf{2} \quad \left\{ \begin{array}{ll} n = \text{even} & \mathbf{3} \otimes \mathbf{3} \to \mathbf{2} \\ & \mathbf{3}' \otimes \mathbf{3}' \to \mathbf{2} \\ n = \text{odd} & \mathbf{3} \otimes \mathbf{3}' \to \mathbf{2} \end{array} \right\} \quad \begin{pmatrix} \alpha_2\beta_2 + \alpha_3\beta_1 + \alpha_1\beta_3 \\ (-1)^n(\alpha_3\beta_3 + \alpha_1\beta_2 + \alpha_2\beta_1) \end{pmatrix},$$

$$\mathbf{3}^{(\prime)} \otimes \mathbf{3}^{(\prime)} \to \mathbf{3}^{(\prime)} \quad \left\{ \begin{array}{ll} n = \text{odd} & \mathbf{3} \otimes \mathbf{3} \to \mathbf{3}' \\ & \mathbf{3} \otimes \mathbf{3}' \to \mathbf{3} \\ & \mathbf{3}' \otimes \mathbf{3}' \to \mathbf{3}' \end{array} \right\} \quad \begin{pmatrix} 2\alpha_1\beta_1 - \alpha_2\beta_3 - \alpha_3\beta_2 \\ 2\alpha_3\beta_3 - \alpha_1\beta_2 - \alpha_2\beta_1 \\ 2\alpha_2\beta_2 - \alpha_3\beta_1 - \alpha_1\beta_3 \end{pmatrix},$$

$$\mathbf{3}^{(\prime)} \otimes \mathbf{3}^{(\prime)} \to \mathbf{3}^{(\prime)} \quad \left\{ \begin{array}{ll} n = \text{even} & \mathbf{3} \otimes \mathbf{3} \to \mathbf{3} \\ & \mathbf{3}' \otimes \mathbf{3}' \to \mathbf{3} \\ & \mathbf{3} \otimes \mathbf{3}' \to \mathbf{3}' \end{array} \right\} \quad \begin{pmatrix} \alpha_2\beta_3 - \alpha_3\beta_2 \\ \alpha_1\beta_2 - \alpha_2\beta_1 \\ \alpha_3\beta_1 - \alpha_1\beta_3 \end{pmatrix}.$$

The A_4 Clebsch-Gordan coefficients can be obtained from the above expressions by simply dropping all primes and identifying the components of the S_4 doublet $\mathbf{2}$ as the $\mathbf{1}''$ and $\mathbf{1}'$ representations of A_4, see Table 4. We thus find for the non-trivial products

$$\begin{aligned}
&\mathbf{1}' \otimes \mathbf{1}'' \to \mathbf{1} && \alpha\beta \,, \\
&\mathbf{1}' \otimes \mathbf{3} \to \mathbf{3} && \alpha \begin{pmatrix} \beta_3 \\ \beta_1 \\ \beta_2 \end{pmatrix}, \\
&\mathbf{1}'' \otimes \mathbf{3} \to \mathbf{3} && \alpha \begin{pmatrix} \beta_2 \\ \beta_3 \\ \beta_1 \end{pmatrix}, \\
&\mathbf{3} \otimes \mathbf{3} \to \mathbf{1} && \alpha_1\beta_1 + \alpha_2\beta_3 + \alpha_3\beta_2 \,, \\
&\mathbf{3} \otimes \mathbf{3} \to \mathbf{1}' && \alpha_3\beta_3 + \alpha_1\beta_2 + \alpha_2\beta_1 \,, \\
&\mathbf{3} \otimes \mathbf{3} \to \mathbf{1}'' && \alpha_2\beta_2 + \alpha_3\beta_1 + \alpha_1\beta_3 \,, \\
&\mathbf{3} \otimes \mathbf{3} \to \mathbf{3} + \mathbf{3} && \begin{pmatrix} 2\alpha_1\beta_1 - \alpha_2\beta_3 - \alpha_3\beta_2 \\ 2\alpha_3\beta_3 - \alpha_1\beta_2 - \alpha_2\beta_1 \\ 2\alpha_2\beta_2 - \alpha_3\beta_1 - \alpha_1\beta_3 \end{pmatrix} + \begin{pmatrix} \alpha_2\beta_3 - \alpha_3\beta_2 \\ \alpha_1\beta_2 - \alpha_2\beta_1 \\ \alpha_3\beta_1 - \alpha_1\beta_3 \end{pmatrix}.
\end{aligned}$$

B Perturbative diagonalisation of M_R

In this Appendix we present a general method for a perturbative diagonalisation of the right-handed neutrino mass matrix and the determination of the PMNS matrix in the diagonal charged lepton mass basis. The method is analogous to the perturbative expansion of the effective neutrino mass matrix developed in [45], which is mainly applicable to the case of a diagonal right-handed neutrino mass matrix as encountered in indirect models. We show that, in the case of the direct models in this paper, it is sufficient to consider the matrix U_R which perturbatively diagonalises the right-handed neutrino mass matrix, since the PMNS matrix is then simply obtained from U_R due to the trivial structure of the Dirac mass matrix.

Writing the matrix U_R as in Eq. (4.6), $U_R = (\Phi_1, \Phi_2, \Phi_3)$, we can express the mass matrix M_R, see Eq. (4.8), as

$$M_R \;=\; U_R^* M_R^{\rm diag} U_R^\dagger \;=\; \sum_i M_i \, \Phi_i^* \Phi_i^\dagger \;, \tag{B.1}$$

where M_i are the eigenvalues of M_R. For small deviations from TB mixing, we can expand this equation in linear approximation around its TB form using

$$M_R = M_R^{\rm TB} + \Delta M_R \;, \qquad M_i \;=\; M_i^{\rm TB} + \Delta M_i \;, \qquad \Phi_i \;=\; \Phi_i^{\rm TB} + \Delta\Phi_i \;. \tag{B.2}$$

Here $M_R^{\rm TB}$ is the part of M_R that does not depend on the small parameter Δ. Its eigenvalues are

$$M_1^{\rm TB} = 3\alpha + \beta - \gamma \;, \qquad M_2^{\rm TB} = \beta + 2\gamma \;, \qquad M_3^{\rm TB} = 3\alpha - \beta + \gamma \;, \tag{B.3}$$

with eigenvectors

$$\Phi_1^{\rm TB} = \frac{1}{\sqrt{6}} \begin{pmatrix} 2 \\ -1 \\ -1 \end{pmatrix} , \qquad \Phi_2^{\rm TB} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} , \qquad \Phi_3^{\rm TB} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix} . \tag{B.4}$$

Following [45], we parameterise $\Delta\Phi_i$ in the basis of these TB column vectors $\Phi_i^{\rm TB}$,

$$\Delta\Phi_i \;=\; \sum_j \alpha_{ij} \Phi_j^{\rm TB} \;. \tag{B.5}$$

The parameters α_{ij}, which are a measure of how much the mixing deviates from the TB pattern, are small. In order to determine their dependence on the input parameters $\alpha, \beta, \gamma, \Delta$, we first observe that U_R must be unitary, i.e.

$$\delta_{ij} \;=\; \left(\Phi_i^{\rm TB} + \sum_k \alpha_{ik} \Phi_k^{\rm TB} \right)^\dagger \left(\Phi_j^{\rm TB} + \sum_l \alpha_{jl} \Phi_l^{\rm TB} \right) \;\approx\; \delta_{ij} + \alpha_{ij}^* + \alpha_{ji} \;, \tag{B.6}$$

where we have dropped second order terms. As a consequence of unitarity we thus get

$$\alpha_{ji} \;\approx\; -\,\alpha_{ij}^* \;. \tag{B.7}$$

Expanding Eq. (B.1) around its TB structure and keeping only terms linear in small deviations, we get

$$\begin{aligned}\Delta M_R &= M_R - M_R^{\rm TB} \\ &\approx \sum_i \left(\Delta M_i\, \Phi_i^{\rm TB}\Phi_i^{{\rm TB}^T} + M_i^{\rm TB}\, \Delta\Phi_i^* \Phi_i^{{\rm TB}^T} + M_i^{\rm TB}\, \Phi_i^{\rm TB}\Delta\Phi_i{}^\dagger\right) \qquad \text{(B.8)} \\ &\approx \sum_i \left(\Delta M_i\, \Phi_i^{\rm TB}\Phi_i^{{\rm TB}^T} + M_i^{\rm TB} \sum_j \alpha_{ij}^* \Phi_j^{\rm TB}\Phi_i^{{\rm TB}^T} + M_i^{\rm TB} \sum_j \Phi_i^{\rm TB}\alpha_{ij}^* \Phi_j^{{\rm TB}^T}\right) .\end{aligned}$$

With ΔM_R corresponding to the TB breaking contribution to M_R, as in Eq. (3.9),

$$\Delta M_R = \Delta \begin{pmatrix} 0 & 1 & -1 \\ 1 & -1 & 0 \\ -1 & 0 & 1 \end{pmatrix}, \qquad \text{(B.9)}$$

it is now possible to calculate the parameters α_{ij} and ΔM_i from Eq. (B.8). Counting the number of unknowns we get 6 real parameters for ΔM_i as well as $3+6$ real parameters for α_{ij} where we have accounted for the unitarity constraint of Eq. (B.7).[6] On the other hand Eq. (B.8) yields 6 complex conditions, 3 from the diagonal entries and 3 from the off-diagonals (ΔM_R is symmetric). As the number of unknowns is bigger than the number of conditions we do not find a unique solution. Note however that the effect of α_{ii} can always be absorbed in ΔM_i. Hence we can remove 3 unknowns by setting $\alpha_{ii} = 0$ without loss of generality.

The remaining 12 unknowns can be determined by sandwiching Eq. (B.8) between $\Phi_k^{{\rm TB}^T}$ and $\Phi_l^{\rm TB}$,

$$\Phi_k^{{\rm TB}^T} \Delta M_R\, \Phi_l^{\rm TB} \approx \left(\Delta M_k \delta_{kl} + M_l^{\rm TB}\, \alpha_{lk}^* + M_k^{\rm TB}\, \alpha_{kl}^*\right) . \qquad \text{(B.10)}$$

Explicit calculation of the left-hand side gives

$$\begin{aligned} 0 &\approx M_1^{\rm TB}\alpha_{12}^* - M_2^{\rm TB}\alpha_{12} , & \text{(B.11)} \\ 0 &\approx M_2^{\rm TB}\alpha_{23}^* - M_3^{\rm TB}\alpha_{23} , & \text{(B.12)} \\ -\sqrt{3}\,\Delta &\approx M_1^{\rm TB}\alpha_{13}^* - M_3^{\rm TB}\alpha_{13} , & \text{(B.13)} \\ 0 &\approx \Delta M_1 \approx \Delta M_2 \approx \Delta M_3 . & \text{(B.14)} \end{aligned}$$

Notice that the TB breaking parameter Δ does not give rise to corrections to the mass eigenvalues in linear approximation. Eqs. (B.11) and (B.12) tell us that $\alpha_{12} = \alpha_{23} = 0$ unless $|M_1^{\rm TB}| = |M_2^{\rm TB}|$ and $|M_2^{\rm TB}| = |M_3^{\rm TB}|$, respectively. Eq. (B.13) can be used to determine the complex valued α_{13} in terms of the parameters α, β, γ and Δ of the right-

[6] Note that α_{ii} must be purely imaginary.

handed neutrino mass matrix M_R. A straightforward but tedious calculation yields

$$\mathrm{Re}\,(\alpha_{13}) \;\approx\; -\frac{\sqrt{3}}{2}\cdot\left[\mathrm{Re}\left(\frac{\Delta}{\beta-\gamma}\right)+\mathrm{Im}\left(\frac{\Delta}{\beta-\gamma}\right)\frac{\mathrm{Im}\left(\frac{3\alpha}{\beta-\gamma}\right)}{\mathrm{Re}\left(\frac{3\alpha}{\beta-\gamma}\right)}\right]\;, \tag{B.15}$$

$$\mathrm{Im}\,(\alpha_{13}) \;\approx\; \frac{\sqrt{3}}{2}\cdot\frac{\mathrm{Im}\left(\frac{\Delta}{\beta-\gamma}\right)}{\mathrm{Re}\left(\frac{3\alpha}{\beta-\gamma}\right)}\;. \tag{B.16}$$

Notice that α_{13} is proportional to the TB violating parameter Δ, which, in the S_4 model, is proportional to the ζ_ν flavon VEV as shown in Eq. (3.11). Once α_{13} is determined, the matrix U_R, and hence the PMNS matrix, are fully determined, as discussed in Section 4.
